Determination of FSP through Solute Exclusion Technique

1° Produce a solution of molecules, concentration $c_1 = \frac{m_1}{V_1}$

2° Add wet porous substance, mass of solids in relation to volume of water $c_2 = \frac{m_2}{V_2}$

3° some of the water coming with the substance dilutes the solution, concentration becomes

$$c_3 = \frac{m_1}{V_3}$$

What is now V_3 ?

That is water volume accessible to the molecules. $V_1 + V_2 = V_3 + V_4$

V_4 is inaccessible water volume

$$V_4 = V_1 + V_2 - V_3 = \frac{m_1}{c_1} + \frac{m_2}{c_2} - \frac{m_1}{c_3}$$

$$FSP \left[\frac{(1)}{(1)} \right] = \frac{V_4 \cdot S_w}{m_2} = S_w \left[\frac{m_1}{m_2} \left(\frac{1}{c_1} - \frac{1}{c_3} \right) + \frac{1}{c_2} \right]$$

V_4 is mass of water in pores inaccessible to molecules

Partial Fractions Decomposition

The ratio changes its values most rapidly in the vicinity of $x = \alpha$, where $h(\alpha) = 0$.

$$f(x) = \frac{g(x)}{h(x)}$$

$$\Rightarrow f(x) = \frac{A_1}{(x-\alpha_1)^{n_1}} + \frac{A_2}{(x-\alpha_2)^{n_2}} + \dots$$

1° How many terms should the Decomposition have?

- as many as distinct roots for $h(x) = 0$

2° What should be the exponents n_1, n_2, \dots ?

- The degree of $h(x) = m \Rightarrow$

$$h(x) = A(x-\alpha_1)^{n_1}(x-\alpha_2)^{n_2} \dots (x-\alpha_k)^{n_k}$$

$$m = n_1 + n_2 + \dots + n_k$$

Example:

$$\frac{1}{r^2 - 2ar + 1} = \frac{1}{h(r)}$$

$$h(\alpha) = 0 \Rightarrow \alpha = a \pm \sqrt{a^2 - 1}$$

$$\frac{1}{h(r)} = \frac{1}{(r-\alpha_1)(r-\alpha_2)} = \frac{A_1}{r-\alpha_1} + \frac{A_2}{r-\alpha_2} = \frac{A_1}{r-a-\sqrt{a^2-1}} + \frac{A_2}{r-a+\sqrt{a^2-1}}$$

$$1 = A_1(r-\alpha_2) + A_2(r-\alpha_1) = A_1(r-a+\sqrt{a^2-1}) + A_2(r-a-\sqrt{a^2-1})$$

$$= (A_1+A_2)(r-a) + (A_1-A_2)\sqrt{a^2-1}$$

$$1 = \text{constant for any } r \Rightarrow A_1 + A_2 = 0 \Rightarrow A_1 = -A_2$$

$$\Rightarrow 1 = 2A_1\sqrt{a^2-1} \Rightarrow A_1 = \frac{1}{2\sqrt{a^2-1}}$$

$$A_2 = -\frac{1}{2\sqrt{a^2-1}}$$
